Review: Bayes risk minimization

- Risk – assign instance to a wrong class

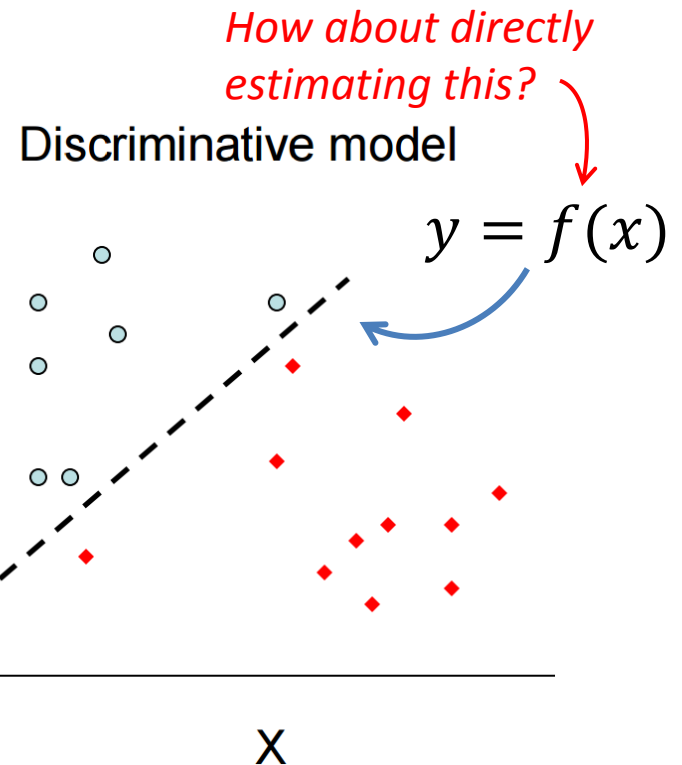

$$-y^* = \operatorname{argmax}_y P(y|X) \quad \text{*Optimal Bayes decision boundary}$$

Discriminative v.s. generative models

All instances are considered for probability density estimation

Generative model

More attention will be put onto the boundary points

Logistic regression

- Summary

$$\begin{aligned} - P(y = 1|X) &= \frac{P(X|y = 1)P(y=1)}{P(X|y = 1)P(y=1)+P(X|y = 0)P(y=0)} \\ &= \frac{1}{1 + \frac{P(X|y = 0)P(y = 0)}{P(X|y = 1)P(y = 1)}} \end{aligned}$$

Logistic regression

- Decision boundary for binary case

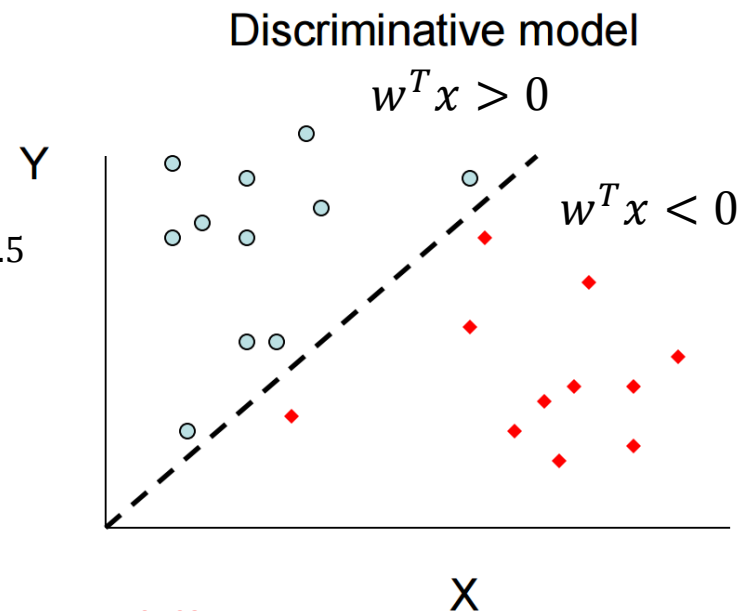

$$- \hat{y} = \begin{cases} 1, & p(y = 1|X) > 0.5 \\ 0, & \text{otherwise} \end{cases}$$

$$\text{i.f.f.} \quad p(y = 1|X) = \frac{1}{1 + \exp(-w^T X)} > 0.5$$

$$\text{i.f.f.} \quad \exp(-w^T X) < 1$$

$$\text{i.f.f.} \quad w^T X > 0$$

$$- \hat{y} = \begin{cases} 1, & w^T x > 0 \\ 0, & \text{otherwise} \end{cases} \quad \leftarrow \text{A linear model!}$$

Which linear classifier do we prefer?

- Choose the one with maximum separation margin

Parameterize the margin

Distance from a point to a line $\frac{|w^T x|}{\sqrt{w^T w}}$

- Margin = $\min_i \frac{y_i w^T x_i}{\sqrt{w^T w}}$

Since $y = \text{sgn}(w^T x)$

The distance can be written as $\frac{y w^T x}{\sqrt{w^T w}}$

Max margin classifier

- $w^* = \operatorname{argmax}_w \min_i \frac{y_i w^T x_i}{\sqrt{w^T w}}$

Max margin classifier

- $\operatorname{argmax}_w \min_i \frac{y_i w^T x_i}{\sqrt{w^T w}}$ is difficult to be optimized in general
 - Insight: $\frac{y_i w^T x_i}{\sqrt{w^T w}}$ is invariant to scaling of w
 - Define $y_i w^T x_i = 1$ for the point that is closest to the surface
 - Then, $\forall i, y_i w^T x_i \geq 1$

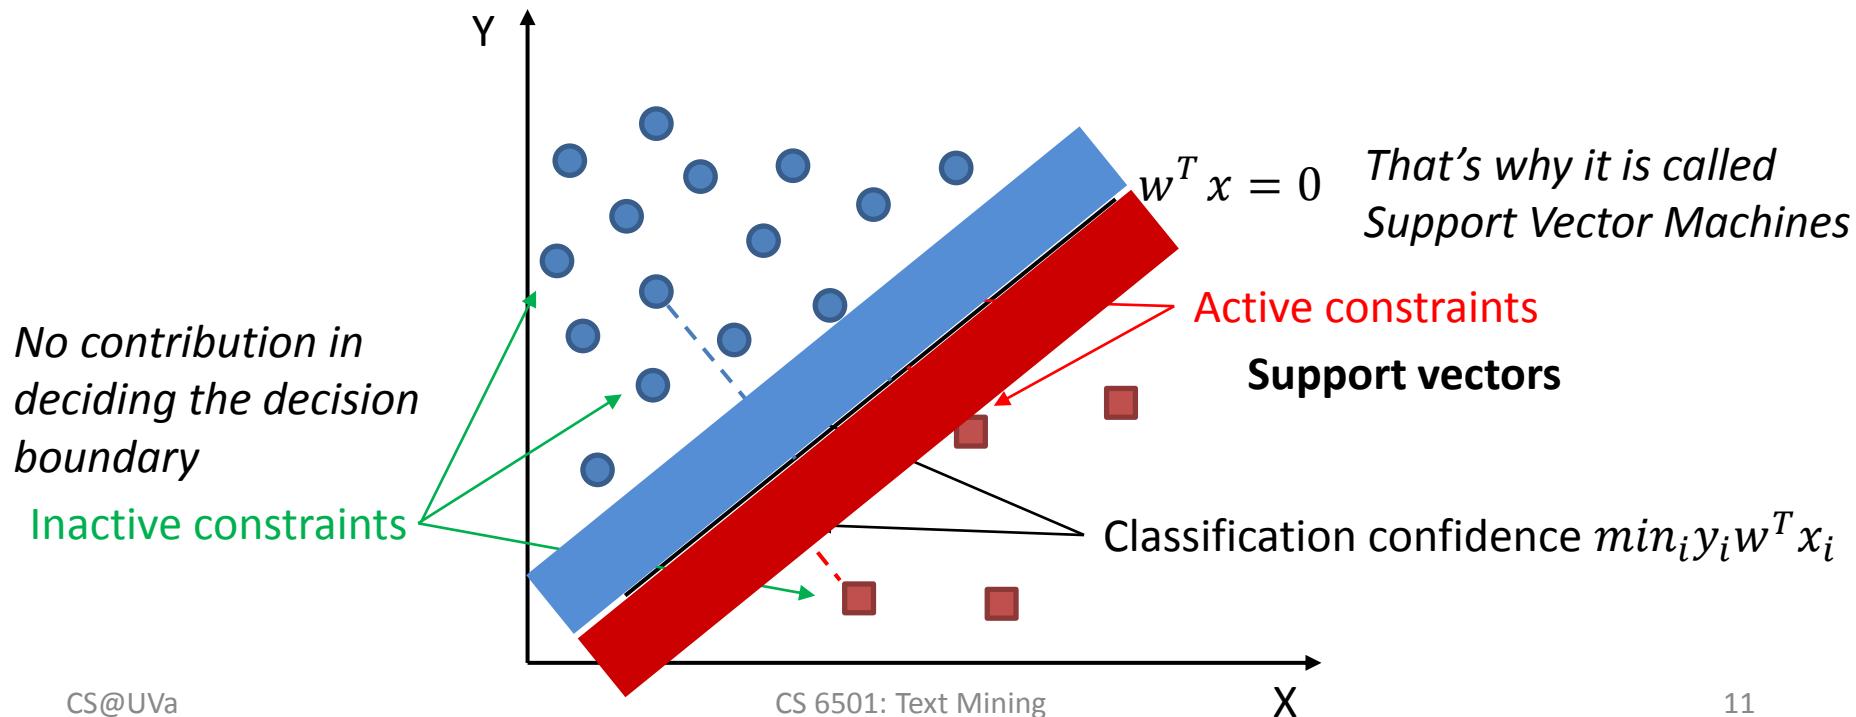

Max margin classifier

$$\operatorname{argmin}_w \frac{1}{\sqrt{w^T w}}$$

$$\text{s.t. } \forall i, y_i w^T x_i \geq 1$$

Quadratic programming!
Easy to solve!

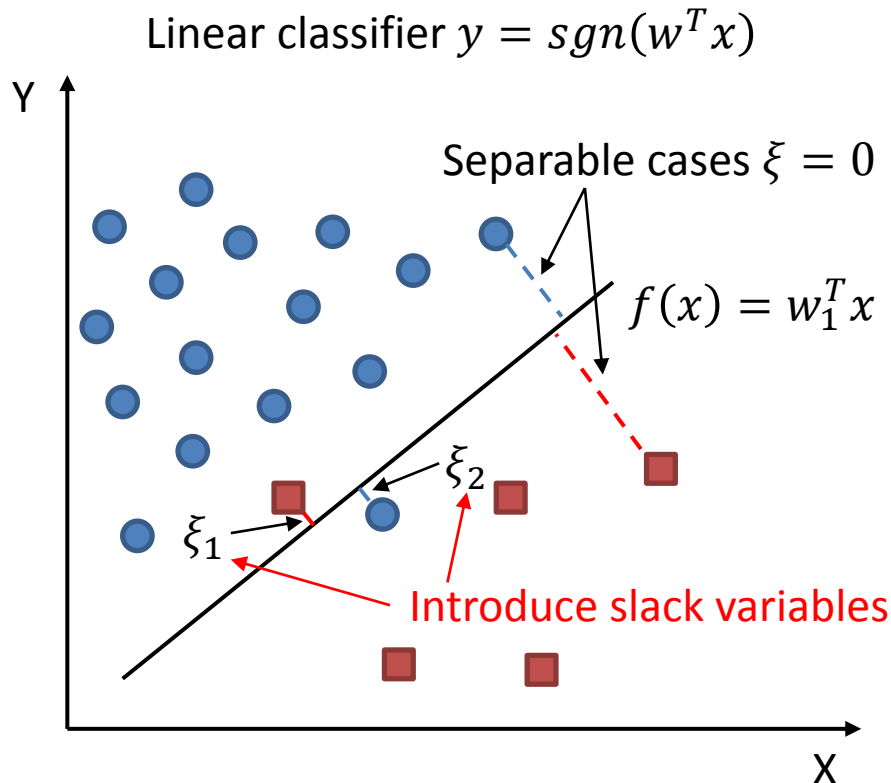

What if the instances are not linearly separable?

- Maximize the margin while minimizing the number of errors made by the classifier?

Soft-margin SVM

- Relax the constraints and penalize the misclassification error

$$\begin{aligned} \argmin_{w, \xi} & w^T w + C \sum_i \xi_i \\ \text{s.t. } & \forall i, y_i w^T x_i \geq 1 - \xi_i \\ & \xi_i \geq 0 \end{aligned}$$

Still a QP!
Easy to optimize!

What kind of loss is SVM optimizing?

$$\begin{aligned} \operatorname{argmin}_{w, \xi} w^T w + C \sum_i \xi_i \\ \text{s.t. } \forall i, y_i w^T x_i \geq 1 - \xi_i \\ \xi_i \geq 0 \end{aligned}$$

$$\operatorname{argmin}_w w^T w + C \sum_i \underline{\max(0, 1 - y_i w^T x_i)}$$

What kind of error is SVM optimizing?

- Hinge loss

Think about logistic regression

- Optimized by maximum a posterior estimator

$$- \operatorname{argmax}_w \sum_x \log p_w(y|x) - \frac{w^T w}{2\sigma^2} \quad \text{Note: } y = \{-1, +1\}$$

➡ $\operatorname{argmin}_w w^T w - C \sum_x \log p_w(y|x)$ Note: $C = 2\sigma^2$

$p_w(y|x) = \frac{1}{1 + \exp(-yw^T x)}$

➡ $\operatorname{argmin}_w \underbrace{w^T w}_{\text{Regularization}} + C \sum_x \underbrace{\log(1 + \exp(-yw^T x))}_{\text{Logistic loss}}$

Different types of classification loss

- Discriminative classifiers aim at optimizing those losses

Pattern Recognition and Machine Learning, p337

What about multi-class classification?

- One v.s. All
 - Simultaneously learn a set of classifiers

What about multi-class classification?

- One v.s. All
 - Simultaneously learn a set of classifiers

For binary classification, we have:

$$\begin{aligned} \operatorname{argmin}_w w^T w + C \sum_i \xi_i \\ \text{s.t. } \forall i, y_i w^T x_i \geq 1 - \xi_i \\ \xi_i \geq 0 \end{aligned}$$

 *Generalize it!*

What about multi-class classification?

- One v.s. All
 - Simultaneously learn a set of classifiers

$$\begin{aligned} \operatorname{argmin}_w \sum_y w_y^T w_y + C \sum_i \sum_{y \neq y_i} \xi_i^y \\ \text{s.t. } \forall i, y \neq y_i, w_{y_i}^T x_i \geq w_y^T x_i + 1 - \xi_i^y \\ \xi_i^y \geq 0 \end{aligned}$$

Scale the margin by the rest classes

Parameter estimation

- A constrained optimization problem

$$\begin{aligned} \operatorname{argmin}_w w^T w + C \sum_i \xi_i \\ \text{s.t. } \forall i, y_i w^T x_i \geq 1 - \xi_i \\ \xi_i \geq 0 \end{aligned}$$

- Can be directly optimized with gradient-based method

- *Chapelle, Olivier. "Training a support vector machine in the primal." Neural Computation 19.5 (2007): 1155-1178.*

$$\operatorname{argmin}_w w^T w + C \sum_i \max(0, 1 - y_i w^T x_i)$$

piece-wise linear

Dual form of SVM

Just to simplify the follow-up derivations

- A constrained optimization problem

Primal

$$\operatorname{argmin}_w \frac{w^T w}{2} + C \sum_i \xi_i$$

Lagrangian multipliers

$$s. t. \quad \forall i, y_i w^T x_i \geq 1 - \xi_i \quad \alpha_i$$
$$\xi_i \geq 0 \quad \beta_i$$

Lagrangian dual

$$L(w, \xi, \alpha, \beta) = \frac{w^T w}{2} + \sum_i (C \xi_i - \alpha_i (y_i w^T x_i - 1 + \xi_i) - \beta_i \xi_i)$$
$$s. t. \quad \forall i, \alpha_i \geq 0, \beta_i \geq 0$$

Dual form of SVM

- Lagrangian dual

$$L(w, \xi, \alpha, \beta) = \frac{w^T w}{2} + \sum_i (C \xi_i - \alpha_i (y_i w^T x_i - 1 + \xi_i) - \beta_i \xi_i)$$

$$s.t. \forall i, \alpha_i \geq 0, \beta_i \geq 0$$

Lemma

$$\max_{\alpha \geq 0, \beta \geq 0} L(w, \xi, \alpha, \beta) = \begin{cases} f(w, \xi) & \text{if } (w, \xi) \text{ is feasible} \\ +\infty & \text{otherwise} \end{cases}$$

We need to maximize $L(w, \xi, \alpha, \beta)$ with respect to (α, β) and minimize it with respect to (w, ξ)

Dual form of SVM

- Lagrangian dual

$$L(w, \xi, \alpha, \beta) = \frac{w^T w}{2} + \sum_i (C\xi_i - \alpha_i(y_i w^T x_i - 1 + \xi_i) - \beta_i \xi_i)$$

$$s.t. \forall i, \alpha_i \geq 0, \beta_i \geq 0$$

$$\frac{\partial L(w, \xi, \alpha, \beta)}{\partial w} = w - \sum_i \alpha_i y_i x_i$$

Set it to zero

$$w = \sum_i \alpha_i y_i x_i$$

take them back to dual form

$$\frac{\partial L(w, \xi, \alpha, \beta)}{\partial \xi_i} = C - \alpha_i - \beta_i$$

$$\alpha_i + \beta_i = C$$

Dual form of SVM

- Lagrangian dual

$$L(\alpha) = \frac{1}{2} \left(\sum_i \alpha_i y_i x_i \right)^T \left(\sum_i \alpha_i y_i x_i \right) - \sum_i \left(\alpha_i \left(y_i \left(\sum_j \alpha_j y_j x_j \right)^T x_i - 1 \right) \right)$$

$s.t. \forall i, 0 \leq \alpha_i \leq C$

Dual form of SVM

- Lagrangian dual

$$L(\alpha) = \sum_i \alpha_i - \frac{1}{2} \sum_{i,j} \alpha_i \alpha_j y_i y_j x_i x_j$$

In dual form, we need to maximize it!

$$s. t. \forall i, 0 \leq \alpha_i \leq C$$

QP again!
Easy to optimize!

Complementary slackness

In the optimal solution: $\alpha_i(y_i w^T x_i - 1 + \xi_i) = 0$

which means $\alpha_i = 0$ if the constraint is satisfied (correct classification)

$\alpha_i > 0$ if the constraint is not satisfied (misclassification)

Sparsity in dual SVM

- Only a few α s can be non-zero

Why dual form SVM?

- Primal SVM v.s. dual SVM
 - Primal: QP in feature space
 - Dual: QP in instance space
 - If we have a lot more features than training instances, dual optimization will be more efficient
 - More importantly, the kernel trick!

Non-linearly separable cases

- Non-linear mapping to linear separable case

Non-linearly separable cases

- Non-linear mapping to linear separable case

Non-linearly separable cases

- Explore new features
 - Use features of features of features....

(x_1, x_2)

feature mapping $\phi(x)$

$$\phi(x) = (x_1, x_2, x_1^2, x_2^2, x_1x_2, \dots, \exp(x_1x_2))$$

*E.g., in polynomial mapping:
#features $\sim O(V^d)$*

Feature space explodes very quickly!

Rethink about dual form SVM

$$\max_{\alpha} \sum_i \alpha_i - \frac{1}{2} \sum_{i,j} \alpha_i \alpha_j y_i y_j \boxed{x_i^T x_j}$$

$$s. t. \forall i, 0 \leq \alpha_i \leq C$$

Take order 2 polynomial as an example:

$$\phi(x, y) = (x^2, y^2, \sqrt{2}xy)$$

If we take the feature mapping first
and then compute the inner product:

$$\phi(x_a, y_a)^T \phi(x_b, y_b) = x_a^2 x_b^2 + y_a^2 y_b^2 + 2x_a x_b y_a y_b$$

If we compute the inner product first:

$$[(x_a, y_a)^T (x_b, y_b)]^2 = x_a^2 x_b^2 + y_a^2 y_b^2 + 2x_a x_b y_a y_b$$

*What we need is only
the inner product
between instances!*

*No need to take
feature mapping at all!*

Rethink about dual form SVM

- Kernel SVM

$$\begin{aligned} \max_{\alpha} \quad & \sum_i \alpha_i - \frac{1}{2} \sum_{i,j} \alpha_i \alpha_j y_i y_j K(x_i, x_j) \\ \text{s.t.} \quad & \forall i, 0 \leq \alpha_i \leq C \end{aligned}$$

- Kernel function

$$K(x_i, x_j) = \phi(x_i)^T \phi(x_j)$$

*$\phi(x)$ is some high dimensional feature mapping,
but never needed to be explicitly defined*

Rethink about dual form SVM

- Kernel SVM

$$\max_{\alpha} \sum_i \alpha_i - \frac{1}{2} \sum_{i,j} \alpha_i \alpha_j y_i y_j K(x_i, x_j)$$

$$s.t. \forall i, 0 \leq \alpha_i \leq C$$

- Decision boundary

- $f(x) = \underline{w}^T \phi(x)$

*We still don't need this
explicit feature mapping!*

*Similarity between a testing
case and support vectors!*

Recap: soft-margin SVM

- Relax the constraints and penalize the misclassification error

$$\begin{aligned} \operatorname{argmin}_{w, \xi} w^T w + C \sum_i \xi_i \\ \text{s.t. } \forall i, y_i w^T x_i \geq 1 - \xi_i \\ \xi_i \geq 0 \end{aligned}$$

Still a QP!
Easy to optimize!

Recap: different types of classification loss

- Discriminative classifiers aim at optimizing those losses

Recap: dual form of SVM

- Lagrangian dual

$$L(\alpha) = \sum_i \alpha_i - \frac{1}{2} \sum_{i,j} \alpha_i \alpha_j y_i y_j x_i^T x_j$$

In dual form, we need to maximize it!

$$s.t. \forall i, 0 \leq \alpha_i \leq C$$

QP again!
Easy to optimize!

Complementary slackness

In the optimal solution: $\alpha_i(y_i w^T x_i - 1 + \xi_i) = 0$

which means $\alpha_i = 0$ if the constraint is satisfied (correct classification)

$\alpha_i > 0$ if the constraint is not satisfied (misclassification)

Rethink about dual form SVM

- Kernel SVM

$$\max_{\alpha} \sum_i \alpha_i - \frac{1}{2} \sum_{i,j} \alpha_i \alpha_j y_i y_j K(x_i, x_j)$$

s. t. $\forall i, 0 \leq \alpha_i \leq C$

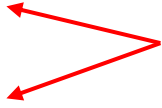

- Decision boundary

- $f(x) = \underline{w^T} \phi(x) = \sum_i \alpha_i y_i \underline{\phi(x_i)^T \phi(x)}$
 $= \sum_i \alpha_i y_i K(x_i, x)$

We still don't need this explicit feature mapping!

Similarity between a testing case and support vectors!

How to construct a kernel

- Sufficient and necessary condition for $K(x, y)$ to be valid kernel
 - Symmetric
 - Semi-positive definite
-  *Just like the requirement for a distance metric*
- Operations that preserve kernel properties
 - $K^*(x, y) = cK(x, y)$, where $c > 0$
 - $K^*(x, y) = K_1(x, y) + K_2(x, y)$
 - $K^*(x, y) = \exp(K(x, y))$
 - $K^*(x, y) = K_1(x, y)K_2(x, y)$

Common kernels

- Polynomials of degree up to d
 - $K(x, y) = (x^T y + 1)^d$
- Radial basis function kernel/Gaussian kernel
 - $K(x, y) = \exp\left(-\frac{(x-y)^T(x-y)}{2\sigma^2}\right)$
 - Polynomials of all orders – recall series expansion

Special kernels for text data

- String kernel

- x and y are two text sequences

- $K(x, y) = \sum_n \boxed{\sum_{u \in A^n} \sum_{i: u=x[i]} \sum_{j: u=y[j]} 1}$

- where A is an finite alphabet of symbols

*N-gram kernel
(length n substrings)*

All character sequence of length n

All occurrences of sequence u in y

All occurrences of sequence u in x

Insight of string kernel:

*Counting the overlapping of all subsequences
with length up to n in x and y*

Lodhi, Huma, et al. "Text classification using string kernels." The Journal of Machine Learning Research 2 (2002): 419-444.
